Near Orbit Near Orbit is a science fiction novel by American writer Kim Stanley Robinson, published in 1989. Plot introduction Near Orbit is set during the late 21st Century. The author is a near-future archaeologist. The book begins with an introduction to the new galactic political and economic alliances the author and his protagonist become involved in during their trip around the galaxy. Plot summary The book follows the career of Pekka Tiemisten, a Finnish-American astrophysicist and near-future archaeologist, who sets out on a mission to investigate the Precambrian Era-level remains of an early alien civilization, on the far side of the galaxy from the Milky Way, and starts a long journey to find out whether the ruins really represent a "new frontier" for human exploration or if they have all been artificially created. The first half of the novel is set in the orbits of the terrestrial planets, where an archaeological expedition is investigating the ruins of a civilization that had left behind enigmatic artifacts. On Earth, the ruins of several millennia before have also started to affect the lives of people living around them: over the past years, the tides have increasingly become unreadable, the population is falling, and something even stranger is happening to the young. Meanwhile, in an orbit around the Sun, a "near-orbiting joint expedition" including all major powers starts to investigate the ruins, in particular to find out if they were the result of an ancient alien civilization or are artificially created. On Earth, the first signs of xenophobia appear: the world's governments are discussing how to respond to the "threat" of the alien ruins, and the political landscape is shifting, with particularly powerful or fanatical groups taking advantage of the situation. The plot then follows a mission to Venus to investigate the Martian ruins, and an expedition to Mercury to investigate the ruins of a now defunct (40,000 years ago) ancient alien civilization. The protagonist Pekka and his allies begin to suspect that the artifacts that they are studying on Mars have been designed to be the "excuse" for the construction of a hyper-advanced "Thule machine", a device first discovered on Saturn, some thousands of years later, by an equally advanced alien civilization. After their discovery, the Thule machine was taken back to Saturn and used to extend their empire to the stars. Structure The novel is written in several parts, which are divided into chapters and sub-chapters.

Short Message Service (SMS) is a telecommunications service that allows users to send and receive short text messages or short messages, typically of 160 characters. Short Message Service (SMS) messages are similar to paging messages in that they are typically delivered to and from a device after the device's user has either actively initiated reception of the message or has chosen to view the short message. More specifically, conventional SMS is a service that allows users to exchange short text messages via mobile phones. The most widely used SMS is based on the IS-41 standard which allows up to 160 characters to be sent. Because of the short format of an SMS message, users require a limited amount of interaction with the service, e.g., an SMS message may not be sent if a phone number is unknown. Thus, SMS is a very efficient service for one-way (point-to-point) text message delivery. As understood, SMS is different from Text messaging (also referred to as "Chat messaging"). More information on SMS can be obtained at [www.smpproject.org](http://www.smpproject.org). Short Messaging System (SMS) messages have long been limited to 160 characters. It is believed that the lack of a desire to send a greater length of text has been the reason that message length has not been increased. This limited length has been due to the requirement that the size of the memory in a mobile phone be relatively small. One area that has not been fully explored is the use of SMS to generate large quantities of traffic. For example, a short text message could be used as a vehicle to obtain a temporary list of phone numbers associated with a group of phone numbers. The numbers in the group are then programmed as "recipients" of the text message and would be sent to the phone number associated with the group when the message is retrieved. The message can be optionally be encrypted and/or stored temporarily, e.g., on a server, in such a way that anyone who knows the phone number of a member of the group can retrieve the message. Optionally, a password can be required to obtain the message. It is believed that the above-mentioned system and others (e.g., pager protocols such as MNP and SIMPLE) lack sufficient security to prevent use by people not associated with the group. Another area that has not been fully explored is the use of SMS to distribute information. For example, a short text message could be used to deliver a listing of all employee phone numbers
